

(a) Projected: with a CogAT comparator

(b) Available now: no comparator

Against the external anchor, the standing score adds $\Delta R^2 = +0.017$ over CogAT alone. Adding the learning-rate readout at the precision it is actually administered at adds $\Delta R^2 = +0.007$; at a 60-trial block it would add +0.015. The learning-rate axis is a real signal that the current block cannot deliver — and lengthening the block would fix its random error while leaving its systematic contamination floor exactly where it is.
