

Cohen's $\kappa = 0.43$ · raw agreement 86%
 A rule fitted to MIMIC her, using her own inputs, reaches only $\kappa = 0.79$:
 that gap is her inconsistency plus the weight she gives things her stated rule omits.

(c) The disagreements are not random

(d) Who is right where they differ

A rule using only the new instrument and MAP agrees with 86% of the officer's decisions ($\kappa = 0.43$), so adopting it would change roughly one file in 7. The disagreements are systematic, not noise. They have two sources: her hard reading gate, which leaves the files the rule would admit and she did not sitting -0.92 SD on MAP reading relative to hers; and, once ability and MAP are removed, a construct-irrelevant impression on which her admits still sit +0.29 SD higher. Where they differ, the rule's picks reach it 40% of the time against 33% for hers.
