

(a) The selective programme sees a slice

(b) What the correction is worth, and what it costs

Run on the selective campus, a validity study would report $r = 0.139$ where the truth over the applicant pool is 0.239 — an understatement of 0.099 caused by who is in the sample, not by how much data was collected. Correcting for it recovers 37% of the gap and buys an assumption about the children who were turned away that cannot be checked. Run on the open-enrolment programme, which currently admits essentially everyone, the same study reports $r = 0.222$ and needs no correction and no assumption. The cheapest defensible validity evidence this programme can buy is to run the study where it is not selecting.
